## Introduction to Machine Learning

“Deep” Neural Networks

Instructor: Po-Chih Kuo

# Roadmap

- Introduction and Basic Concepts
- Regression
- Bayesian Classifiers
- Decision Trees
- Linear Classifier
- Neural Networks
- Deep Neural Networks
- Convolutional Neural Networks
- Reinforcement Learning
- KNN
- Model Selection and Evaluation
- Clustering
- Data Exploration & Dimensionality reduction

# Outline

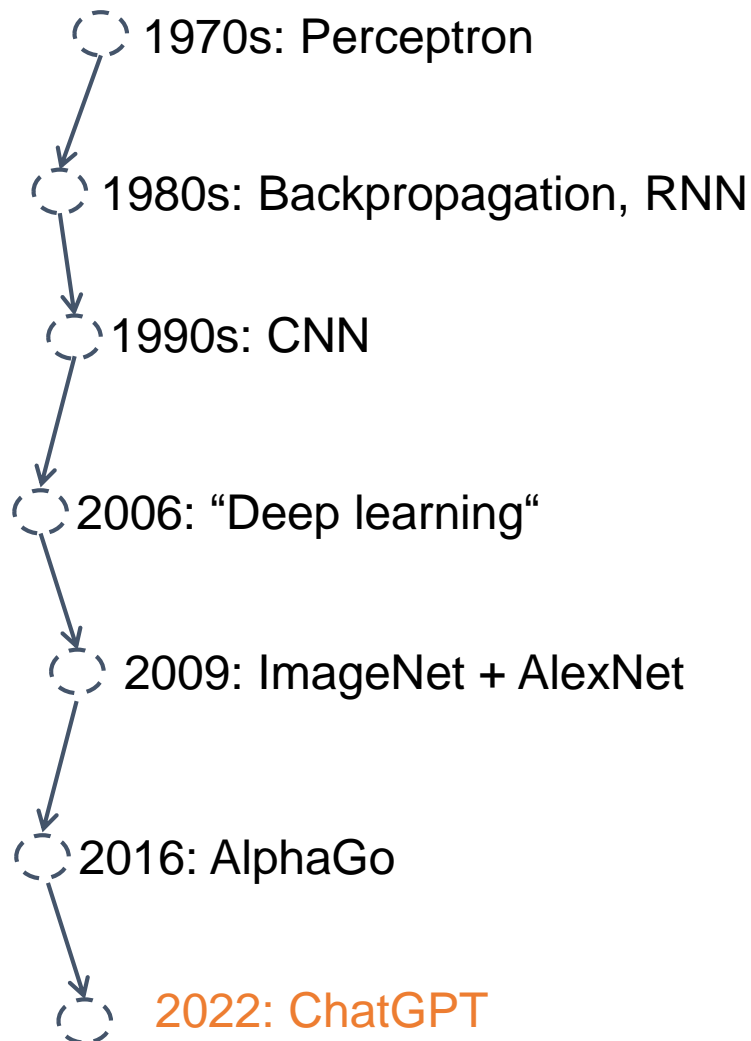

- Why deep?

- Optimization

- Regularization (Overfitting problem)

Tricks!

# Why Deep Learning?

## Deep learning:

- Has won numerous pattern recognition competitions
- Does so with minimal feature engineering

This wasn't always the case!

Since 1980s: Form of models hasn't changed much, but lots of new tricks...

- More hidden units
- Better (online) optimization
- New nonlinear functions (ReLUs)
- Faster computers (CPUs and GPUs)

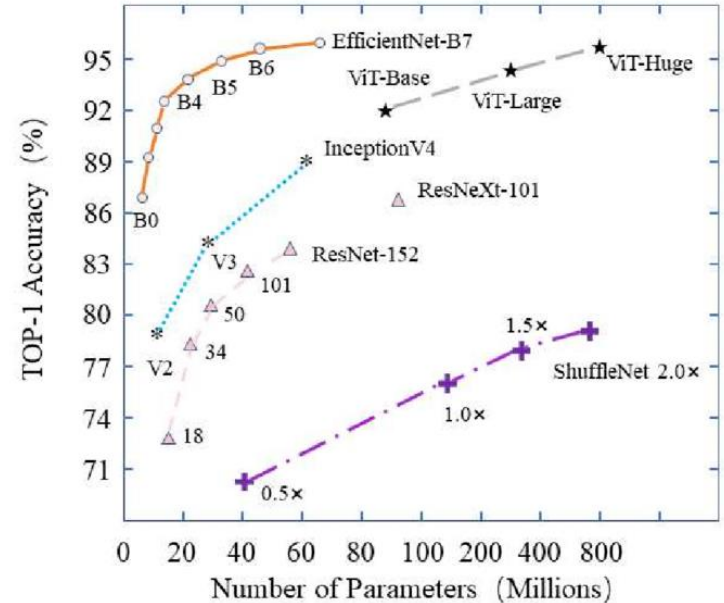

# Performance vs Sample Size

# Parameters vs Accuracy on ImageNet

(Canziani 2016)

(Li 2021)

# Machine Learning = Learning Representations

- **The traditional model of pattern recognition (since the late 50's)**
  - Fixed/engineered features (or fixed kernel) + trainable classifier

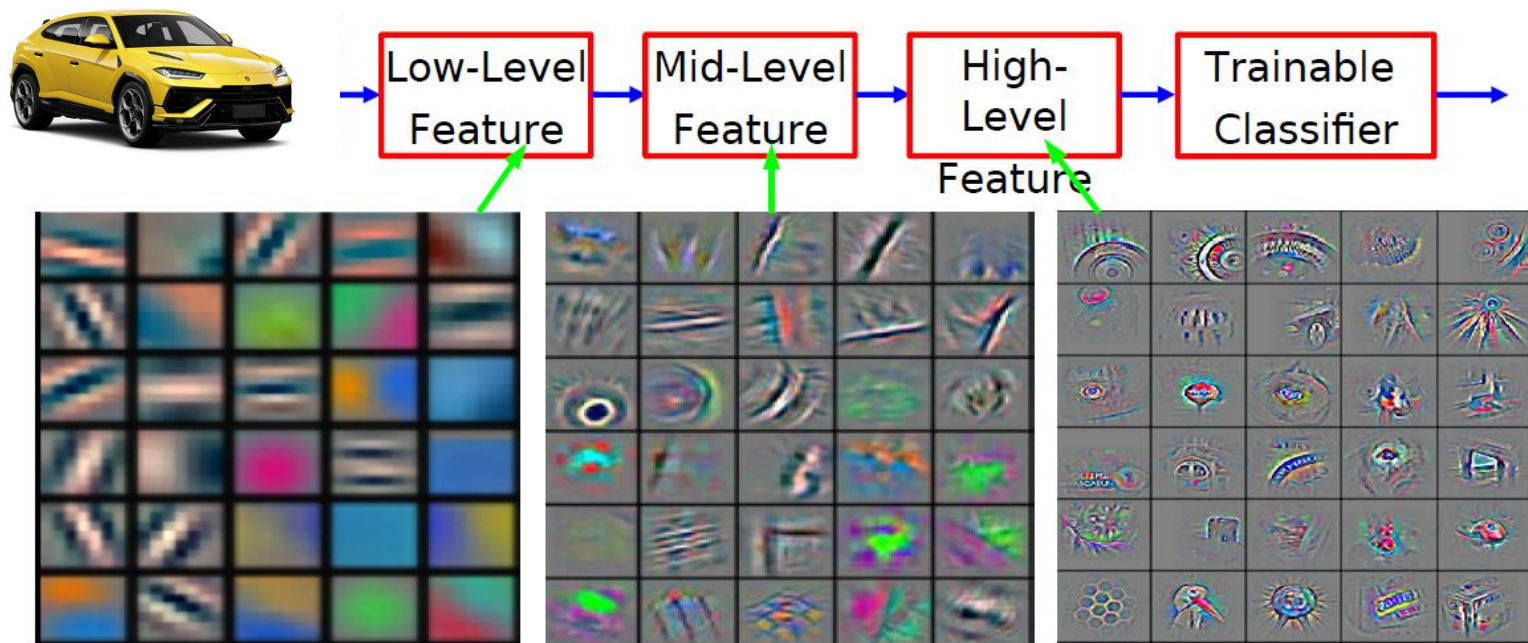

An example we showed in SVM

- **End-to-end learning / Feature learning / Deep learning**
  - Trainable features (or kernel) + trainable classifier

# Deep Learning = Learning Hierarchical Representations

Feature visualization of convolutional net trained on ImageNet from [Zeiler & Fergus 2013]

# Hierarchical representation

- Hierarchy of representations with increasing level of abstraction
- Each stage is a kind of trainable feature transform
- Image recognition
  - Pixel → edge → texton → motif → part → object
- Text
  - Character → word → word group → clause → sentence → story
- Speech
  - Sample → spectral band → sound → ... → phone → phoneme → word

# Which Models are Deep?

## MLP, SVM, or DT

- 2-layer perceptrons are not deep
  - Because there is no feature hierarchy
- SVMs and Kernel methods are not deep
  - Layer1: kernels; layer2: linear
  - The first layer is “trained” using the samples as templates for the kernel functions.
- Decision trees are not deep
  - No hierarchy of features. All decisions are made in the input space

# Outline

- Why deep?
- Optimization
- Regularization (Overfitting problem)

# Optimization

- Vanishing Gradient Problem
- Stochastic Gradient Descent (SGD)
- Momentum Method
- Adaptive Learning Methods (AdaGrad, RMSProp, Adam)

# Vanishing Gradient Problem

- Back propagation uses chain rule.
  - Chain rule multiplies derivatives
- If these derivatives are between 0 and 1 the product vanishes as the chain gets longer.
- Sigmoid activation function leads to this problem.
- Saturating: After some epochs that learning happens fast, the value saturates, and it takes much time to update the weights, because the value of gradient is small.

Sigmoid

# Relu (Rectified Linear Units) function

- Avoids Vanishing Gradient Problem
  - Fast to compute
  - Biological reason
- The formula is simple:  $\max(0, z)$ .

$$\frac{d}{dx} \text{ReLU}(x) = \begin{cases} 0, & \text{if } x < 0, \\ 1, & \text{otherwise.} \end{cases}$$

# Batch Gradient Descent

---

**Algorithm 1** Batch Gradient Descent at Iteration  $k$

---

**Require:** Learning rate  $\epsilon_k$

**Require:** Initial Parameter  $\theta$

- 1: **while** stopping criteria not met **do**
  - 2:   Compute gradient estimate over  $N$  examples:
  - 3:    $\hat{\mathbf{g}} \leftarrow +\frac{1}{N} \nabla_{\theta} \sum_i L(f(\mathbf{x}^{(i)}; \theta), \mathbf{y}^{(i)})$
  - 4:   Apply Update:  $\theta \leftarrow \theta - \epsilon \hat{\mathbf{g}}$
  - 5: **end while**
- 

- Advantage: Gradient estimates are stable
- Problem: Need to compute gradients over the entire training for one update

$\epsilon_k$  is learning rate at step  $k$

In practice the learning rate is decayed linearly till iteration  $\tau$

$$\epsilon_k = (1 - \alpha)\epsilon_0 + \alpha\epsilon_{\tau} \text{ with } \alpha = \frac{k}{\tau}$$

# Stochastic Gradient Descent

---

**Algorithm 2** Stochastic Gradient Descent at Iteration  $k$

---

**Require:** Learning rate  $\epsilon_k$

**Require:** Initial Parameter  $\theta$

- 1: **while** stopping criteria not met **do**
  - 2:   Sample example  $(\mathbf{x}^{(i)}, \mathbf{y}^{(i)})$  from training set
  - 3:   Compute gradient estimate:
  - 4:    $\hat{\mathbf{g}} \leftarrow +\nabla_{\theta} L(f(\mathbf{x}^{(i)}; \theta), \mathbf{y}^{(i)})$
  - 5:   Apply Update:  $\theta \leftarrow \theta - \epsilon \hat{\mathbf{g}}$
  - 6: **end while**
- 

Problem: Gradient estimates can be very noisy

# Minibatching

- Use larger mini-batches
- Advantage: Computation time per update does not depend on number of training examples  $N$
- This allows convergence on extremely large datasets

# Momentum

- The Momentum method is a method to accelerate learning using SGD
- SGD suffers in the following scenarios:
  - Loss surface has high curvature
  - The gradients are very noisy

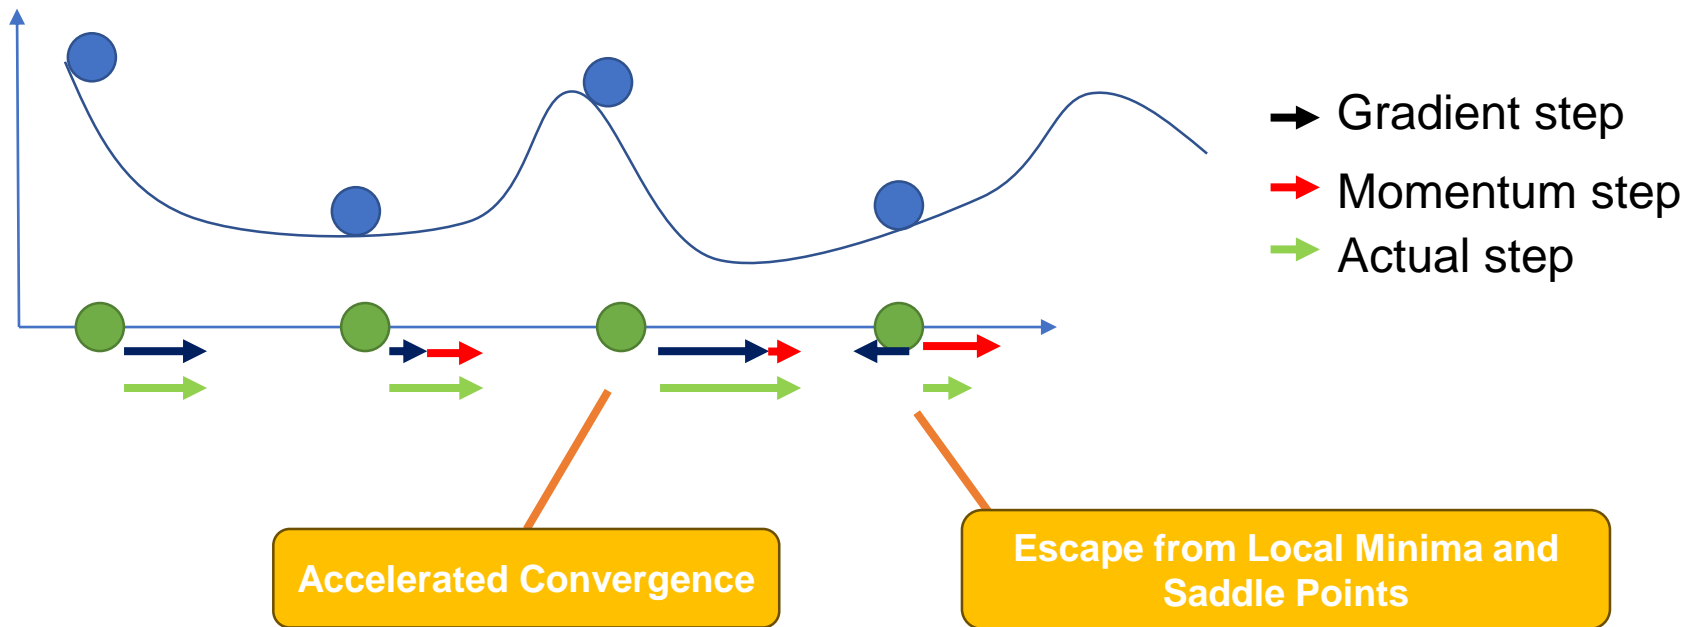

# Momentum

- Introduce a new variable  $\mathbf{v}$ , the velocity
- We think of  $\mathbf{v}$  as the direction and speed by which the parameters move as the learning dynamics progresses

$$\mathbf{v} \leftarrow \alpha \mathbf{v} - \epsilon \nabla_{\theta} \left( L(f(\mathbf{x}^{(i)}; \theta), \mathbf{y}^{(i)}) \right)$$

- Update rule:  $\theta \leftarrow \theta + \mathbf{v}$
- Usually values for  $\alpha$  are set high  $\approx 0.9$

# SGD with Momentum

---

**Algorithm 2** Stochastic Gradient Descent with Momentum

---

**Require:** Learning rate  $\epsilon_k$

**Require:** Momentum Parameter  $\alpha$

**Require:** Initial Parameter  $\theta$

**Require:** Initial Velocity  $\mathbf{v}$

- 1: **while** stopping criteria not met **do**
  - 2:   Sample example  $(\mathbf{x}^{(i)}, \mathbf{y}^{(i)})$  from training set
  - 3:   Compute gradient estimate:
  - 4:    $\hat{\mathbf{g}} \leftarrow +\nabla_{\theta} L(f(\mathbf{x}^{(i)}; \theta), \mathbf{y}^{(i)})$
  - 5:   Compute the velocity update:
  - 6:    $\mathbf{v} \leftarrow \alpha \mathbf{v} - \epsilon \hat{\mathbf{g}}$
  - 7:   Apply Update:  $\theta \leftarrow \theta + \mathbf{v}$
  - 8: **end while**
- 

Reduction of Oscillations

# Adaptive Learning Rate Methods

- Motivation
  - Till now we assign the same learning rate to all features
  - If the features vary in importance and frequency, why is this a good idea? It's probably not!

# AdaGrad

- Idea: Downscale a model parameter by square-root of sum of squares of all its historical values
- Parameters that have large partial derivative of the loss  
→ learning rates for them are rapidly declined

---

## Algorithm 4 AdaGrad

---

**Require:** Global Learning rate  $\epsilon$ , Initial Parameter  $\theta$ ,  $\delta$

Initialize  $\mathbf{r} = 0$

- 1: **while** stopping criteria not met **do**
  - 2:     Sample example  $(\mathbf{x}^{(i)}, \mathbf{y}^{(i)})$  from training set
  - 3:     Compute gradient estimate:  $\hat{\mathbf{g}} \leftarrow +\nabla_{\theta} L(f(\mathbf{x}^{(i)}; \theta), \mathbf{y}^{(i)})$
  - 4:     Accumulate:  $\mathbf{r} \leftarrow \mathbf{r} + \hat{\mathbf{g}} \odot \hat{\mathbf{g}}$
  - 5:     Compute update:  $\Delta\theta \leftarrow -\frac{\epsilon}{\delta + \sqrt{\mathbf{r}}} \odot \hat{\mathbf{g}}$
  - 6:     Apply Update:  $\theta \leftarrow \theta + \Delta\theta$
  - 7: **end while**
-

# RMSProp

Root **Mean** Squared Propagation

- AdaGrad is good when the objective is convex.
- AdaGrad might shrink the learning rate too aggressively, we want to keep the history in mind
- We can adapt it to perform better in non-convex settings by accumulating an exponentially decaying **average** of the gradient
- It was proposed in a slide in Geoffrey Hinton's coursera course

---

**Algorithm 5** RMSProp

---

**Require:** Global Learning rate  $\epsilon$ , decay parameter  $\rho$ ,  $\delta$ , Initial Parameter  $\theta$   
Initialize  $\mathbf{r} = 0$

- 1: **while** stopping criteria not met **do**
  - 2:     Sample example  $(\mathbf{x}^{(i)}, \mathbf{y}^{(i)})$  from training set
  - 3:     Compute gradient estimate:  $\hat{\mathbf{g}} \leftarrow +\nabla_{\theta} L(f(\mathbf{x}^{(i)}; \theta), \mathbf{y}^{(i)})$
  - 4:     Accumulate:  $\mathbf{r} \leftarrow \rho \mathbf{r} + (1 - \rho) \hat{\mathbf{g}} \odot \hat{\mathbf{g}}$
  - 5:     Compute update:  $\Delta \theta \leftarrow -\frac{\epsilon}{\delta + \sqrt{\mathbf{r}}} \odot \hat{\mathbf{g}}$
  - 6:     Apply Update:  $\theta \leftarrow \theta + \Delta \theta$
  - 7: **end while**
-

# Adam: ADAdaptive Moments

- We could have used RMSProp with momentum
- Use of Momentum with rescaling is not well motivated
- Adam is like RMSProp with Momentum but with bias correction terms for the first and second moments

---

**Algorithm 7** RMSProp with Nesterov

---

**Require:**  $\epsilon$  (set to 0.0001), decay rates  $\rho_1$  (set to 0.9),  $\rho_2$  (set to 0.9),  $\theta$ ,  $\delta$

Initialize moments variables  $\mathbf{s} = \mathbf{0}$  and  $\mathbf{r} = \mathbf{0}$ , time step  $t = 0$

```
1: while stopping criteria not met do
2:   Sample example  $(\mathbf{x}^{(i)}, \mathbf{y}^{(i)})$  from training set
3:   Compute gradient estimate:  $\hat{\mathbf{g}} \leftarrow +\nabla_{\theta} L(f(\mathbf{x}^{(i)}; \theta), \mathbf{y}^{(i)})$ 
4:    $t \leftarrow t + 1$ 
5:   Update:  $\mathbf{s} \leftarrow \rho_1 \mathbf{s} + (1 - \rho_1) \hat{\mathbf{g}}$ 
6:   Update:  $\mathbf{r} \leftarrow \rho_2 \mathbf{r} + (1 - \rho_2) \hat{\mathbf{g}} \odot \hat{\mathbf{g}}$ 
7:   Correct Biases:  $\hat{\mathbf{s}} \leftarrow \frac{\mathbf{s}}{1 - \rho_1^t}, \hat{\mathbf{r}} \leftarrow \frac{\mathbf{r}}{1 - \rho_2^t}$ 
8:   Compute Update:  $\Delta\theta = -\epsilon \frac{\hat{\mathbf{s}}}{\sqrt{\hat{\mathbf{r}} + \delta}}$ 
9:   Apply Update:  $\theta \leftarrow \theta + \Delta\theta$ 
10: end while
```

---

Ref: Alec Radford

# Regularization

- In general: any method to **prevent overfitting** or help the optimization
- Specifically: additional **terms** in the **training** optimization objective to prevent overfitting or help the optimization

# Classical regularization

- L2 regularization
  - **L2 = weight decay**
  - Regularization term that penalizes big weights, added to the objective function

$$\min_{\theta} \hat{L}_R(\theta) = \boxed{\hat{L}(\theta)} + \frac{\alpha}{2} \|\theta\|_2^2$$

$w^*$   $\tilde{w}$

- L1 regularization

$$\min_{\theta} \hat{L}_R(\theta) = \hat{L}(\theta) + \alpha \|\theta\|_1$$

# Other types of regularizations

- Data augmentation
- Early stopping
- Dropout
- Batch Normalization

# Data augmentation

- Adding noise to the input: a special kind of augmentation
- Be careful about the transformation applied:
  - Example: classifying 'b' and 'd' or classifying '6' and '9'

Original	Flip	Rotation	Random crop
<ul style="list-style-type: none"> <li>• Image without any modification</li> </ul>	<ul style="list-style-type: none"> <li>• Flipped with respect to an axis for which the meaning of the image is preserved</li> </ul>	<ul style="list-style-type: none"> <li>• Rotation with a slight angle</li> <li>• Simulates incorrect horizon calibration</li> </ul>	<ul style="list-style-type: none"> <li>• Random focus on one part of the image</li> <li>• Several random crops can be done in a row</li> </ul>
Color shift	Noise addition	Information loss	Contrast change
<ul style="list-style-type: none"> <li>• Nuances of RGB is slightly changed</li> <li>• Captures noise that can occur with light exposure</li> </ul>	<ul style="list-style-type: none"> <li>• Addition of noise</li> <li>• More tolerance to quality variation of inputs</li> </ul>	<ul style="list-style-type: none"> <li>• Parts of image ignored</li> <li>• Mimics potential loss of parts of image</li> </ul>	<ul style="list-style-type: none"> <li>• Luminosity changes</li> <li>• Controls difference in exposition due to time of day</li> </ul>

Q: What does data augmentation do for structured data?

# Early stopping

- Idea: don't train the network to too small training error
- Recall overfitting: Larger the hypothesis set (feature set), easier to find a hypothesis that fits the difference between training and testing errors.
- Prevent overfitting: do not push the hypothesis too much; use validation error to decide when to stop

# Early stopping as a regularizer

Early stopping

L2 regularization

# Dropout

- Dropout refers to dropping out units
- Temporarily remove a node and all its incoming/outgoing connections resulting in a thinned network
- Each node is retained with a fixed probability (typically  $p = 0.5$ ) for hidden nodes and  $p = 0.8$  for input nodes

# Batch Normalization (BN)

- To normalize the layers' inputs by re-centering and re-scaling.
- It was proposed by Sergey Ioffe and Christian Szegedy in 2015
- $B$  to denote a mini-batch of size  $m$

$$\mu_B = \frac{1}{m} \sum_{i=1}^m x_i, \text{ and } \sigma_B^2 = \frac{1}{m} \sum_{i=1}^m (x_i - \mu_B)^2.$$

$$\hat{x}_i^{(k)} = \frac{x_i^{(k)} - \mu_B^{(k)}}{\sqrt{\sigma_B^{(k)^2} + \epsilon}}, \text{ where } k \in [1, d] \text{ and } i \in [1, m]$$

$\mu_B^{(k)}$  and  $\sigma_B^{(k)^2}$  are the per-dimension mean and variance, respectively.

[Batch Normalization: Accelerating Deep Network Training ...](#)

by S Ioffe · 2015 · Cited by 58315 — **Batch Normalization** allows us to use much higher learning rates and be less careful about initialization. It also acts as a regularizer. In some ...

# Why BN?

- BN reduces *Covariate Shift*.
  - The change in distribution of activation of a component. By using BN, each neuron's activation becomes (more or less) a Gaussian distribution.
- Covariate Shift is undesirable, because the later layers have to keep adapting to the change of the type of distribution.
- BN reduces effects of exploding and vanishing gradients, because every becomes roughly normal distributed.

# Other benefits of BN

- BN reduces training times and allows higher learning rates
  - Less Covariate Shift, less exploding/vanishing gradients.
- BN reduces demand for regularization (e.g. dropout).
  - Because the means and variances are calculated over batches and therefore every normalized value depends on the current batch. I.e. the network can no longer just memorize values and their correct answers.
- BN enables training with saturating nonlinearities in deep networks, e.g. sigmoid.
  - Because the normalization prevents them from getting stuck in saturating ranges

# Possible Hierarchical Features

But...we got something like this

Let's get back to this in the next lecture !
